## The Low Prevalence Effect (LPE)

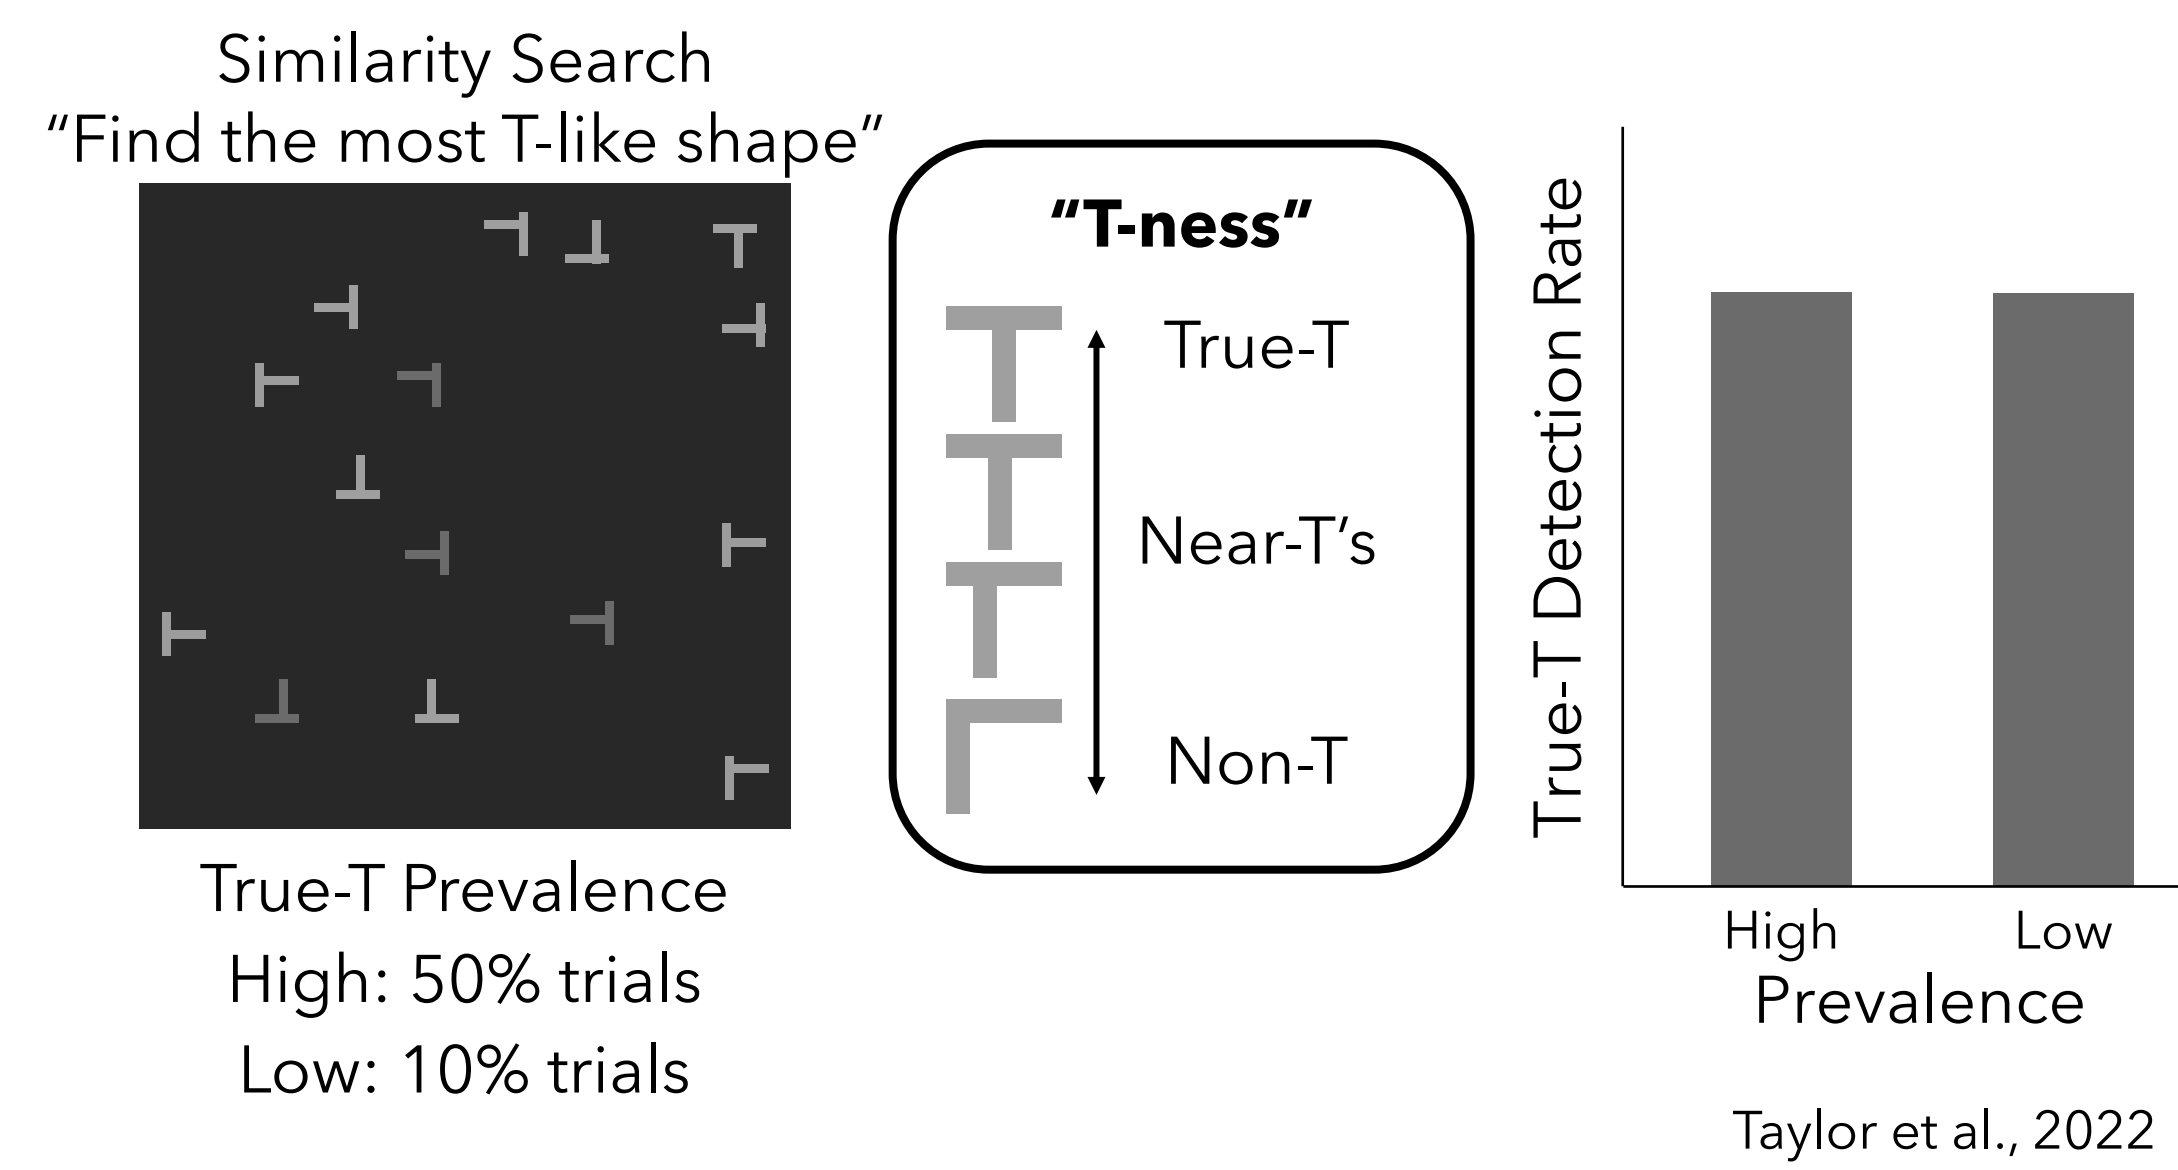

### Rare targets are frequently missed

If you don't find it often, you often don't find it

The LPE is highly resistant to interventions

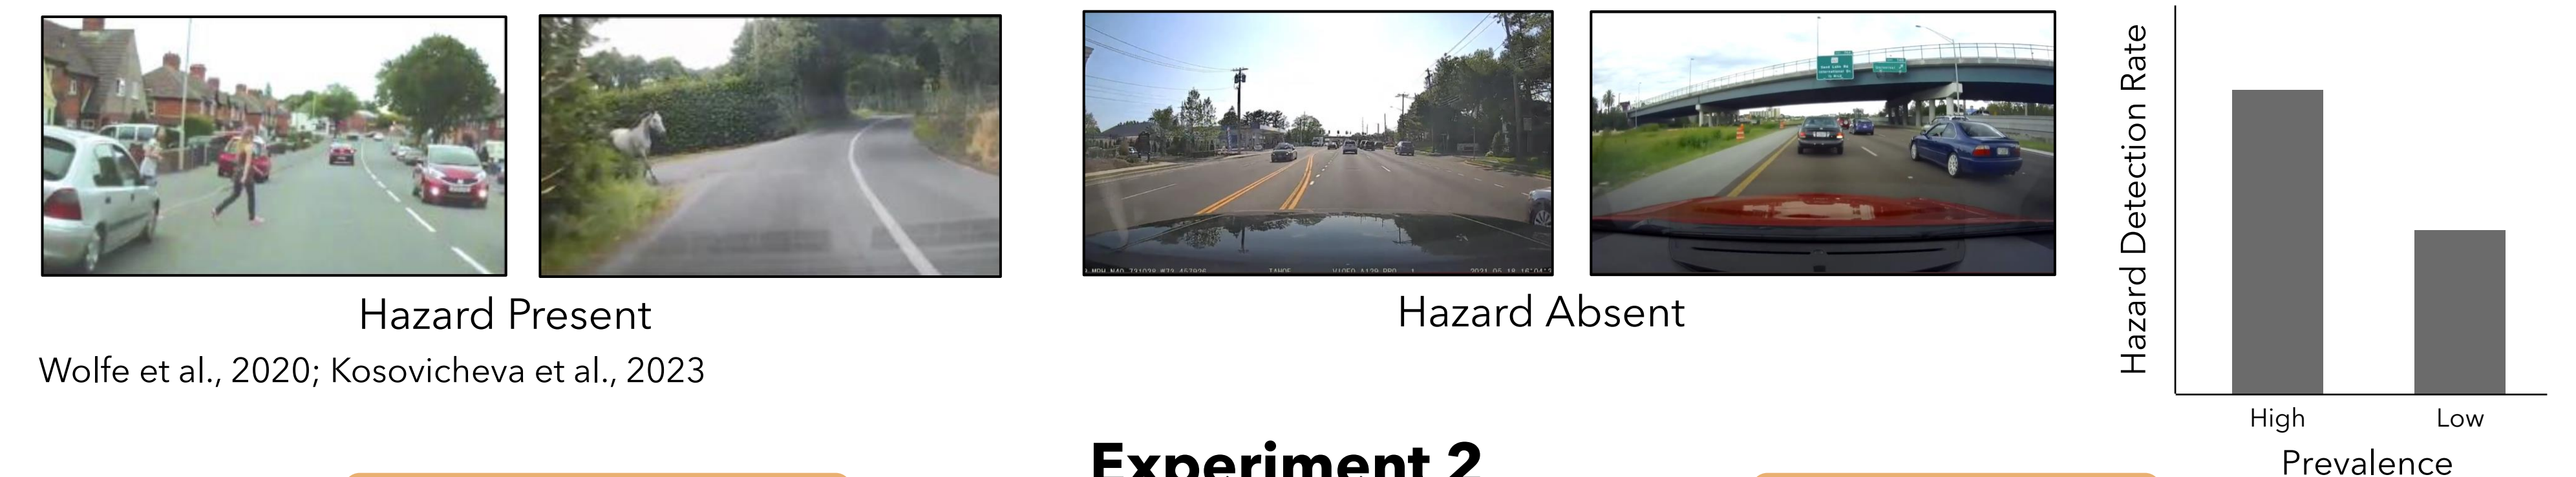

### Similarity search: a possible way to eliminate the LPE?

Does similarity search translate to decisions you need to make about the selected target?

## Does similarity search translate to naturalistic scenarios?

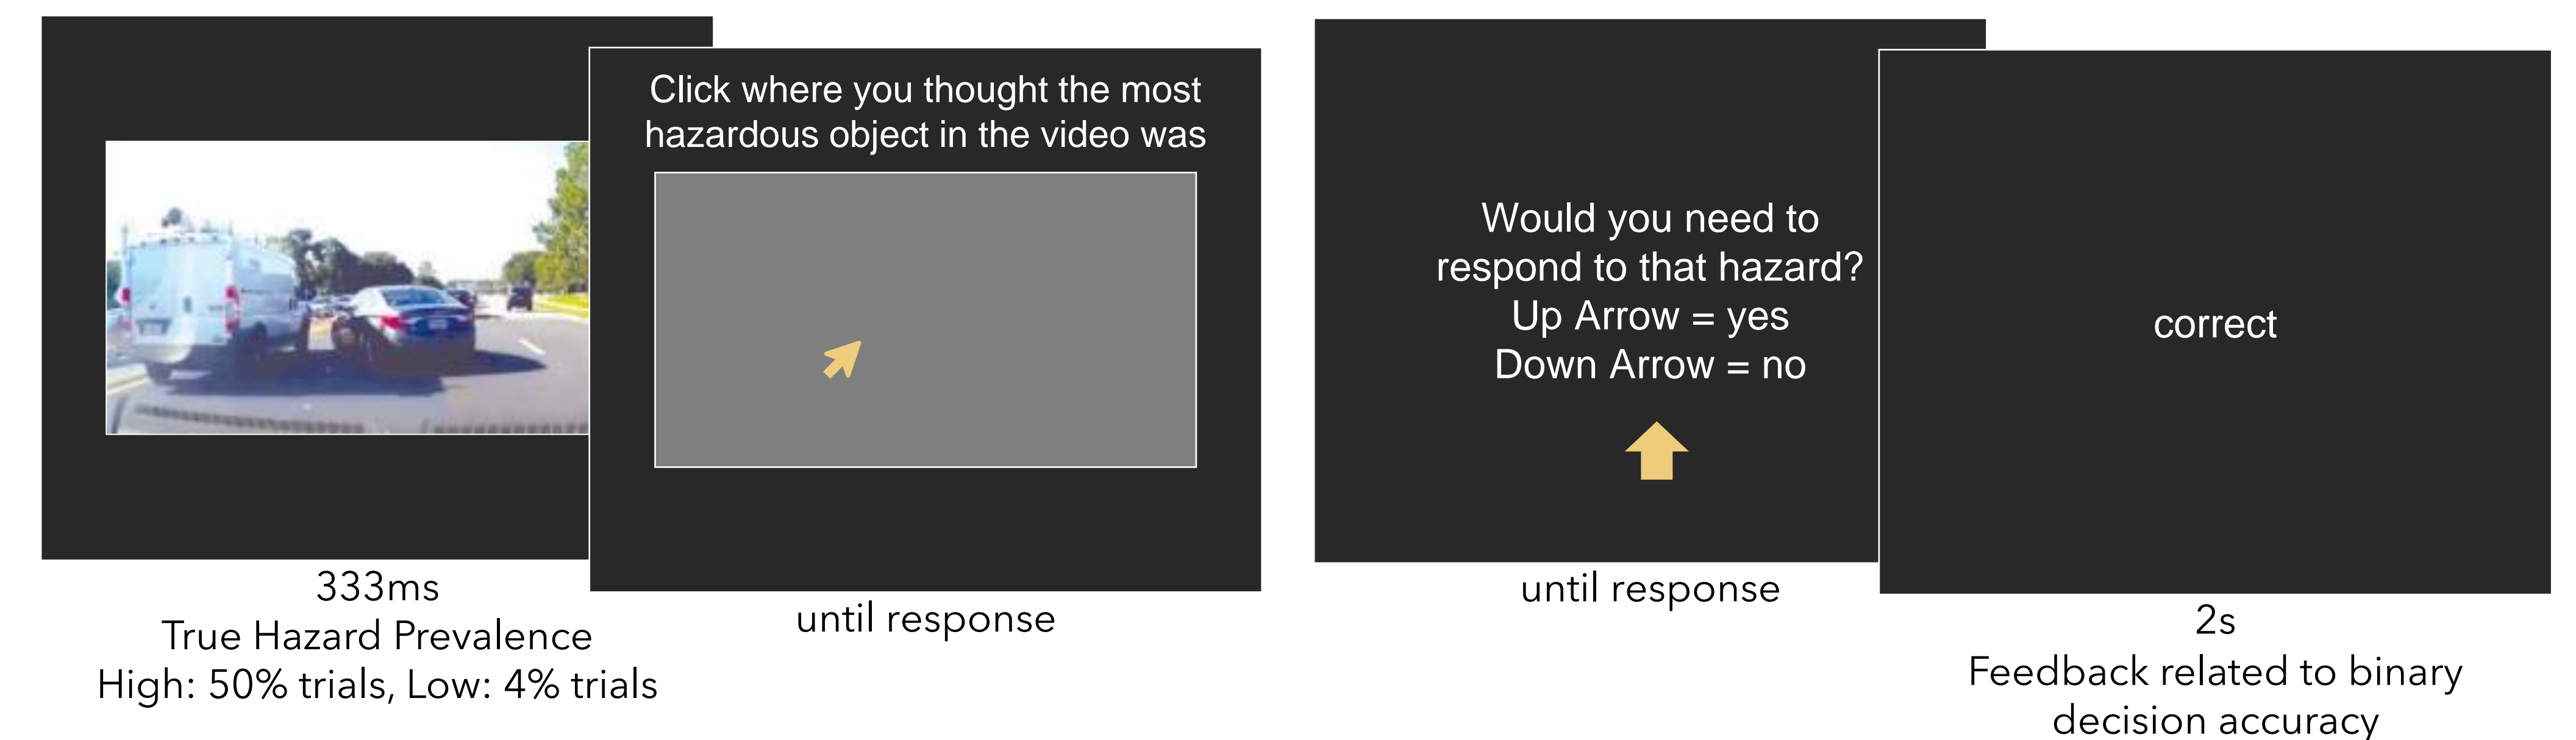

### Observers miss rare road hazards in natural videos, despite target complexity and variability

### Hazard Localization

### Experiment 2

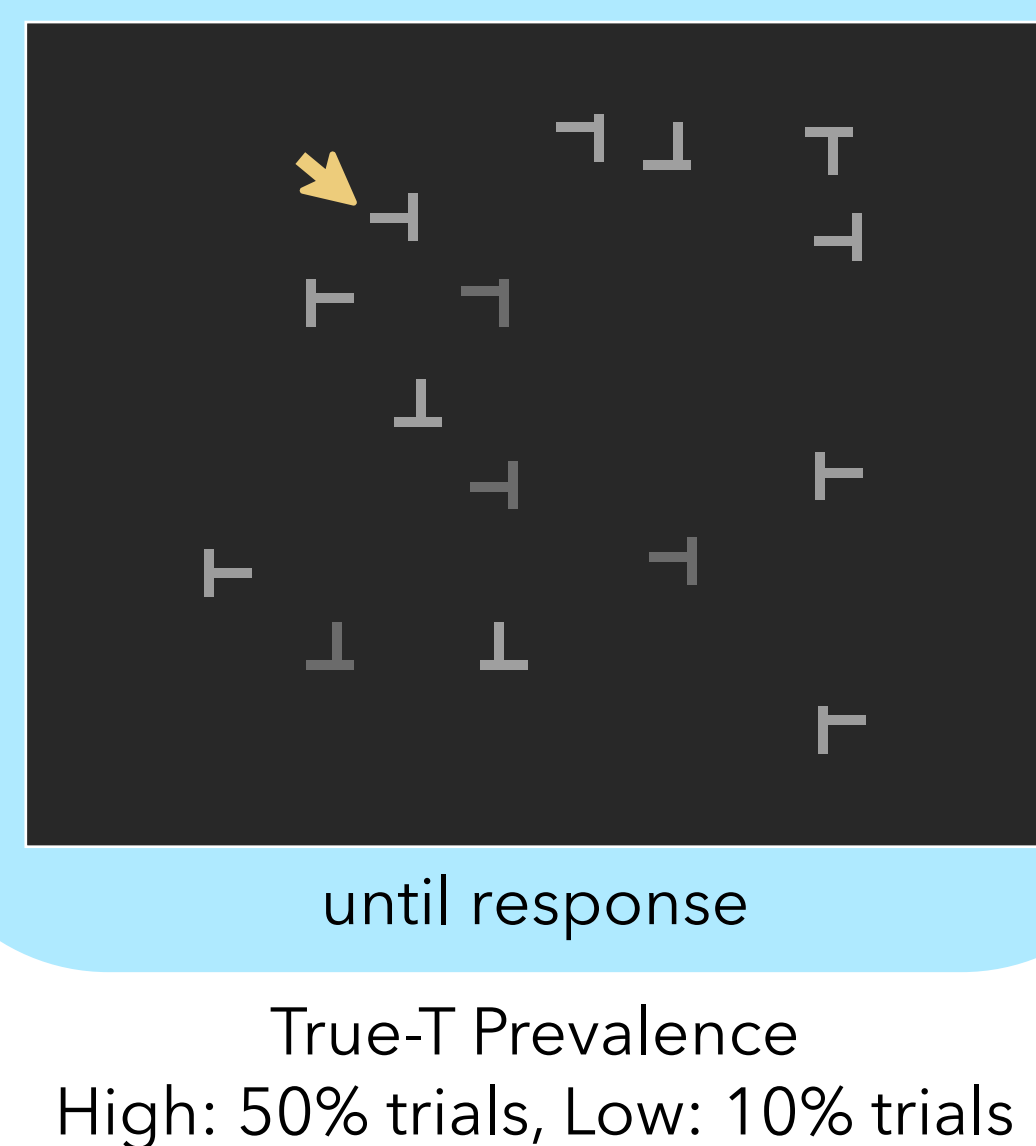

### Binary Decision

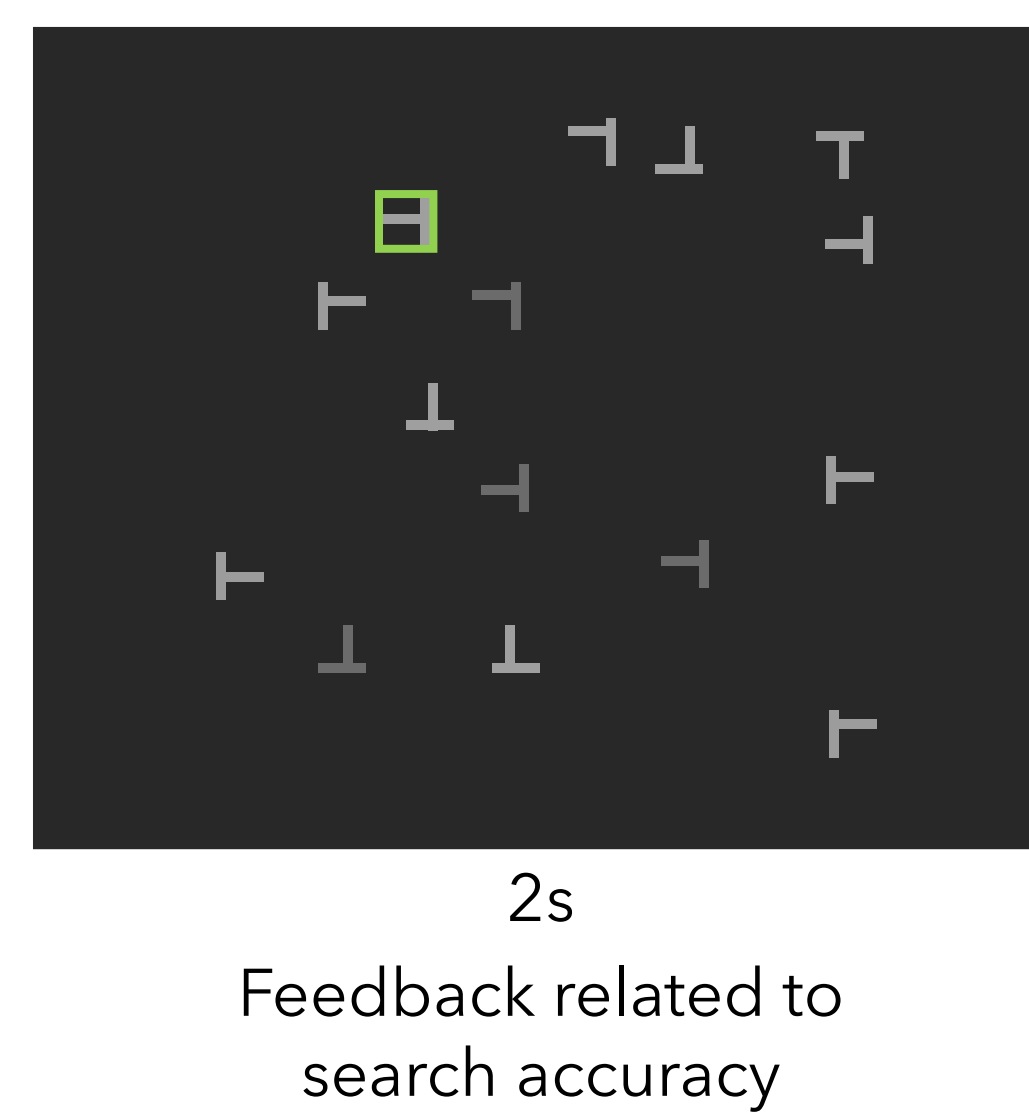

## Does similarity search translate to binary decisions?

### Experiment 1

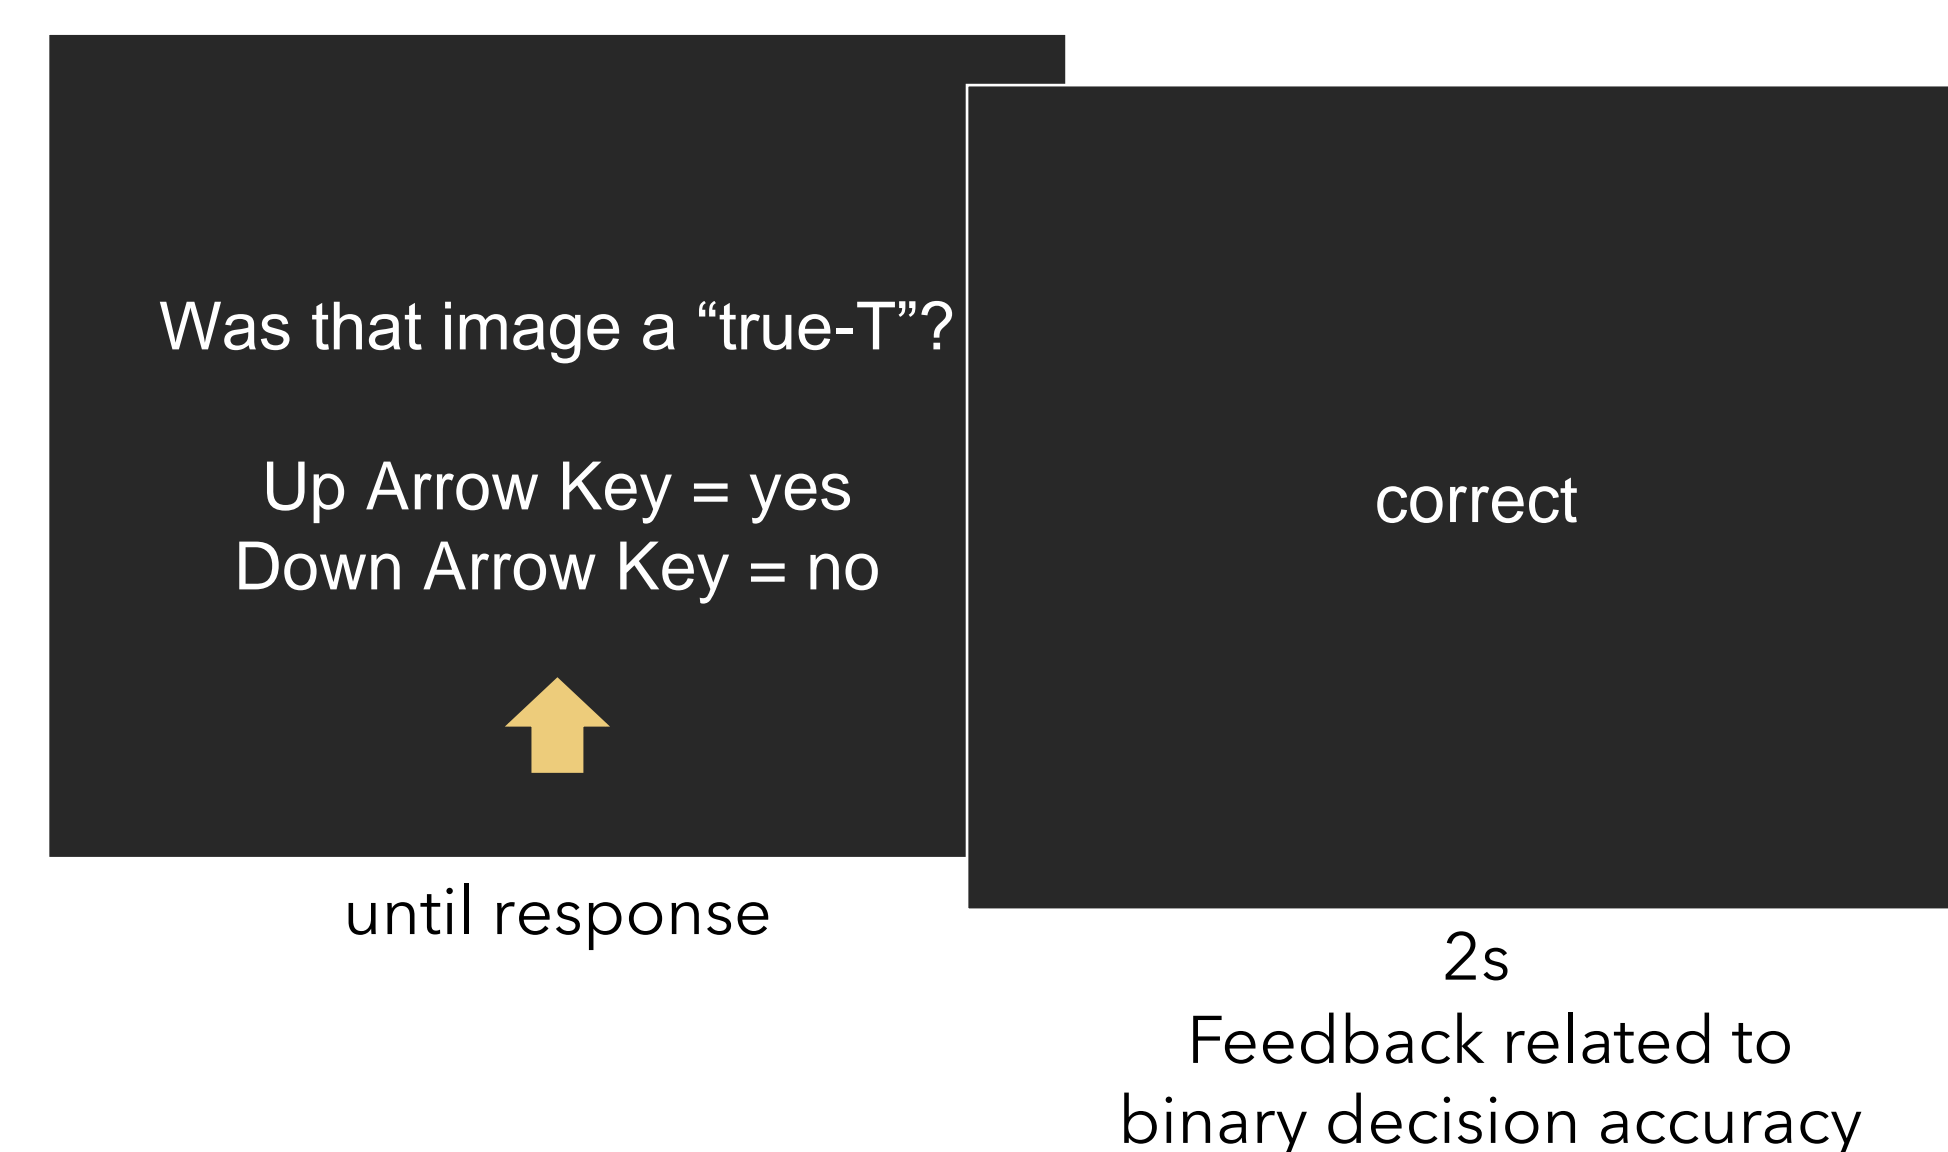

#### Similarity Search Display

#### Similarity Search Only

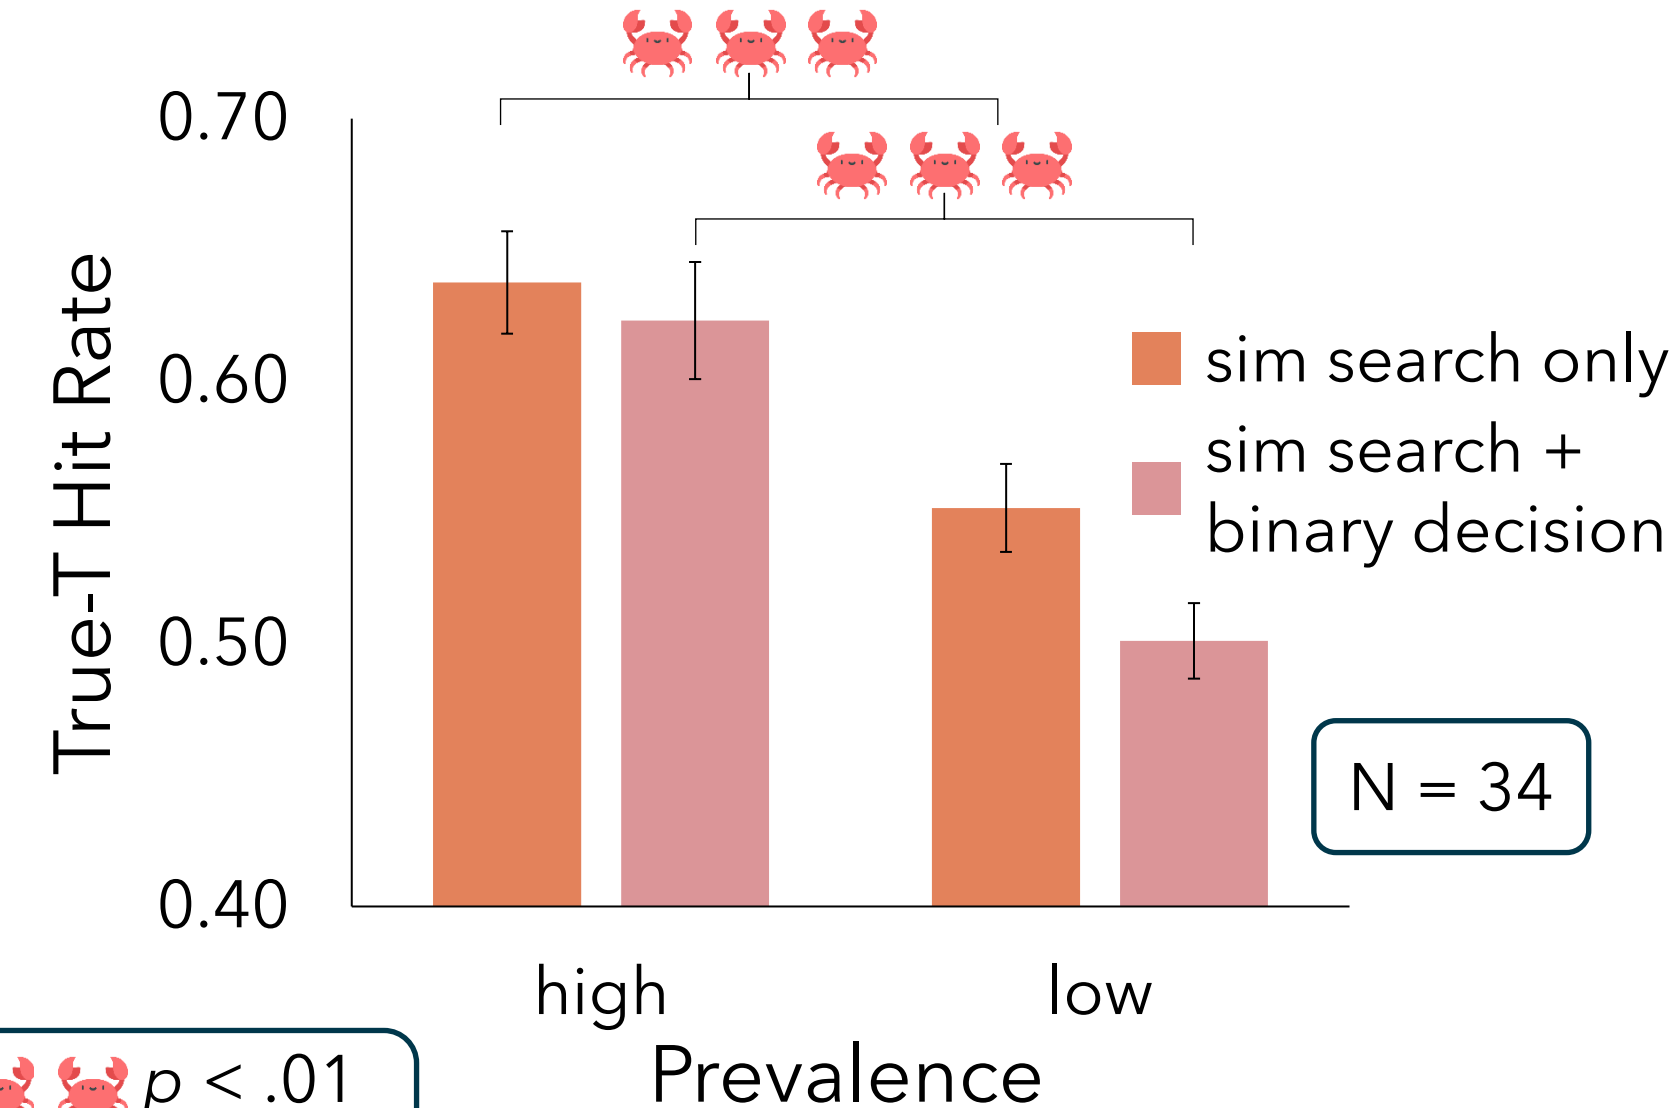

#### Similarity Search + Binary Decision

## Experiment 1 Results

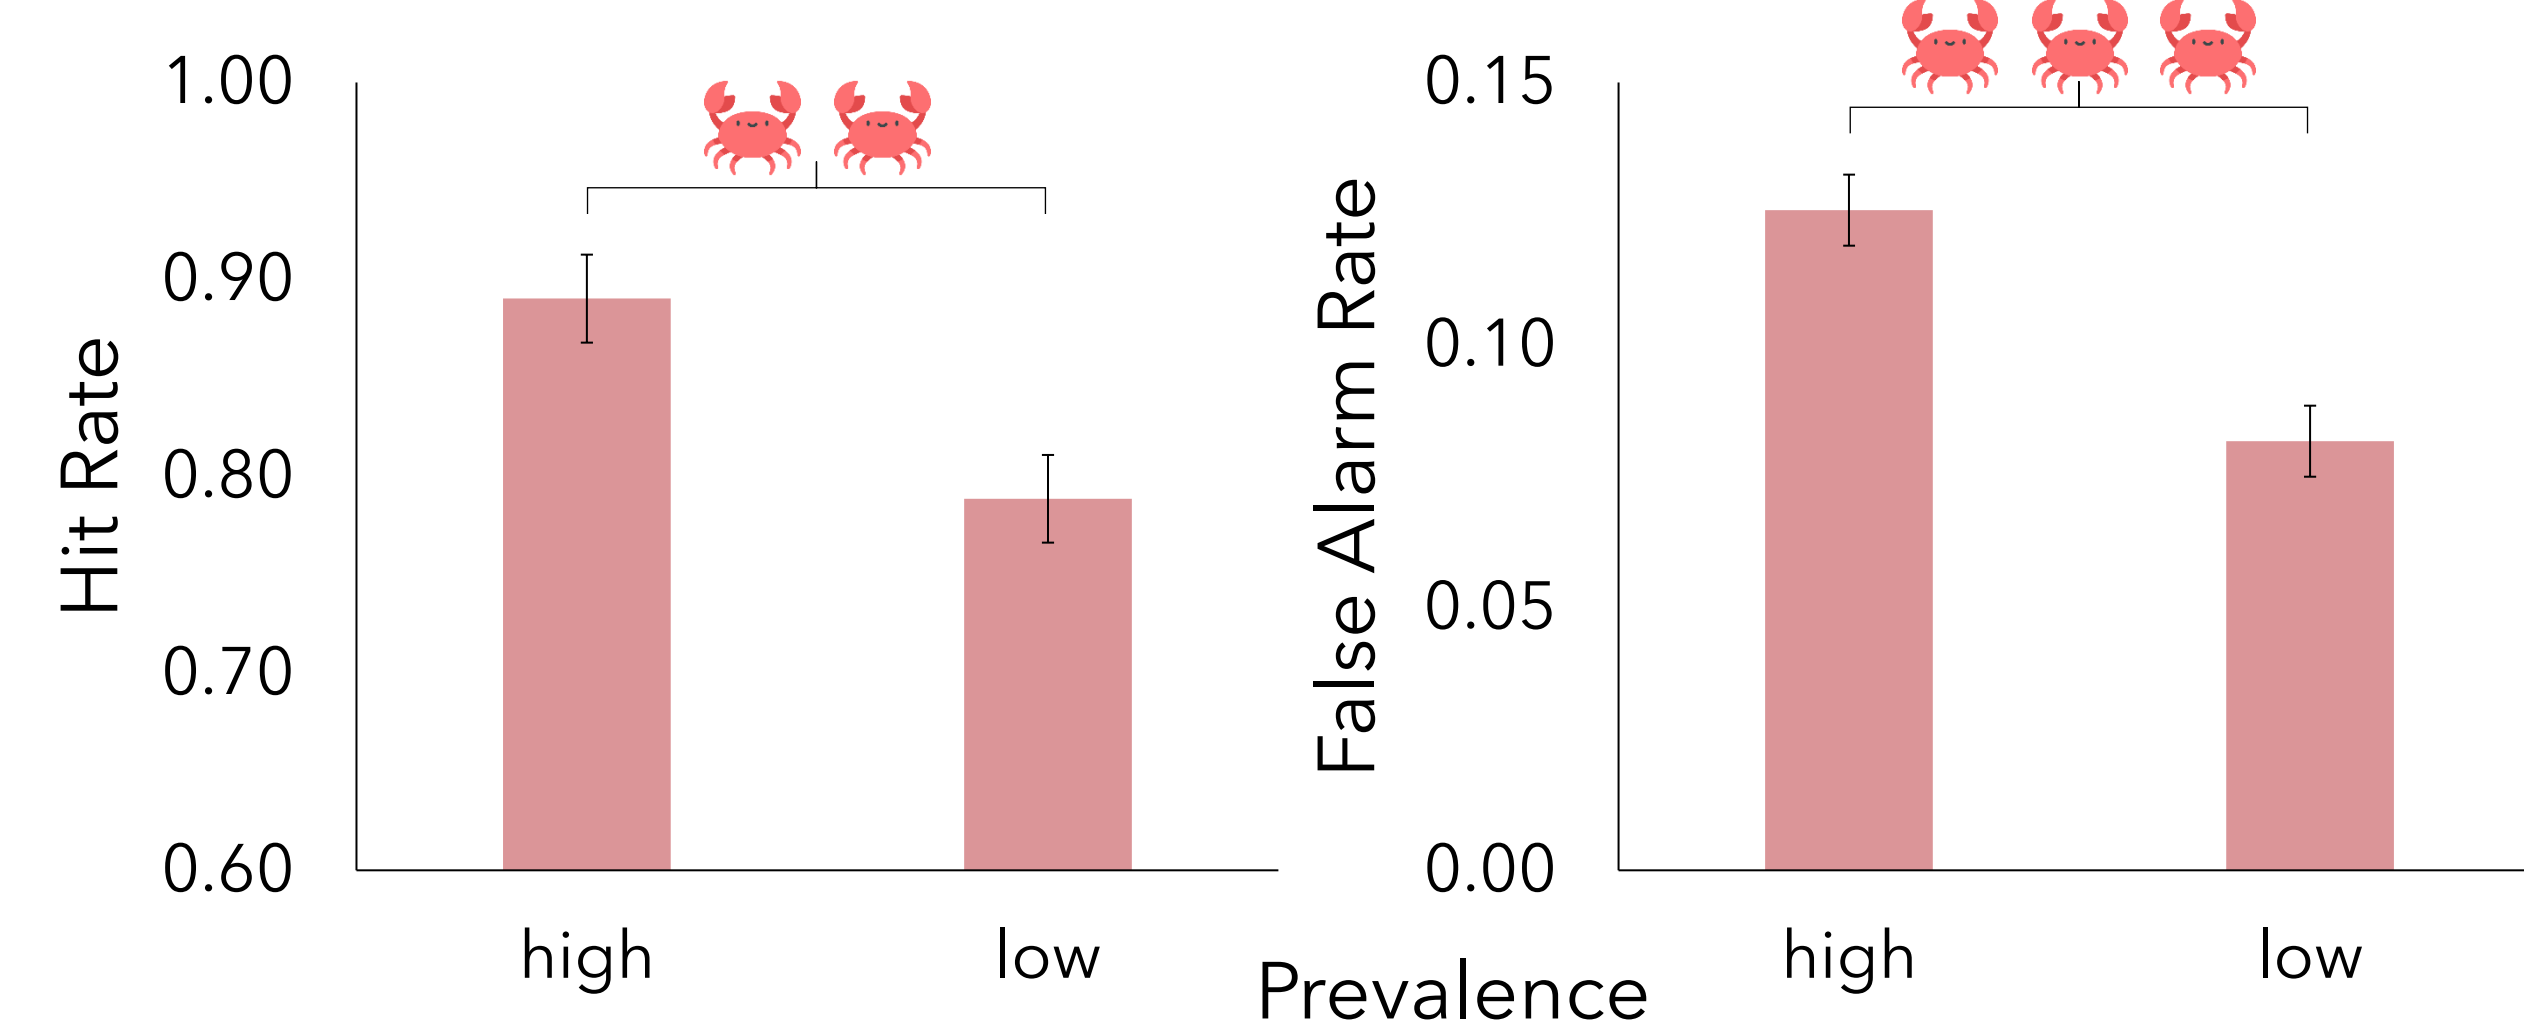

### Similarity Search Performance

$p < .01$   
 $p < .001$

LPE for both tasks

### Binary Decision Task Performance

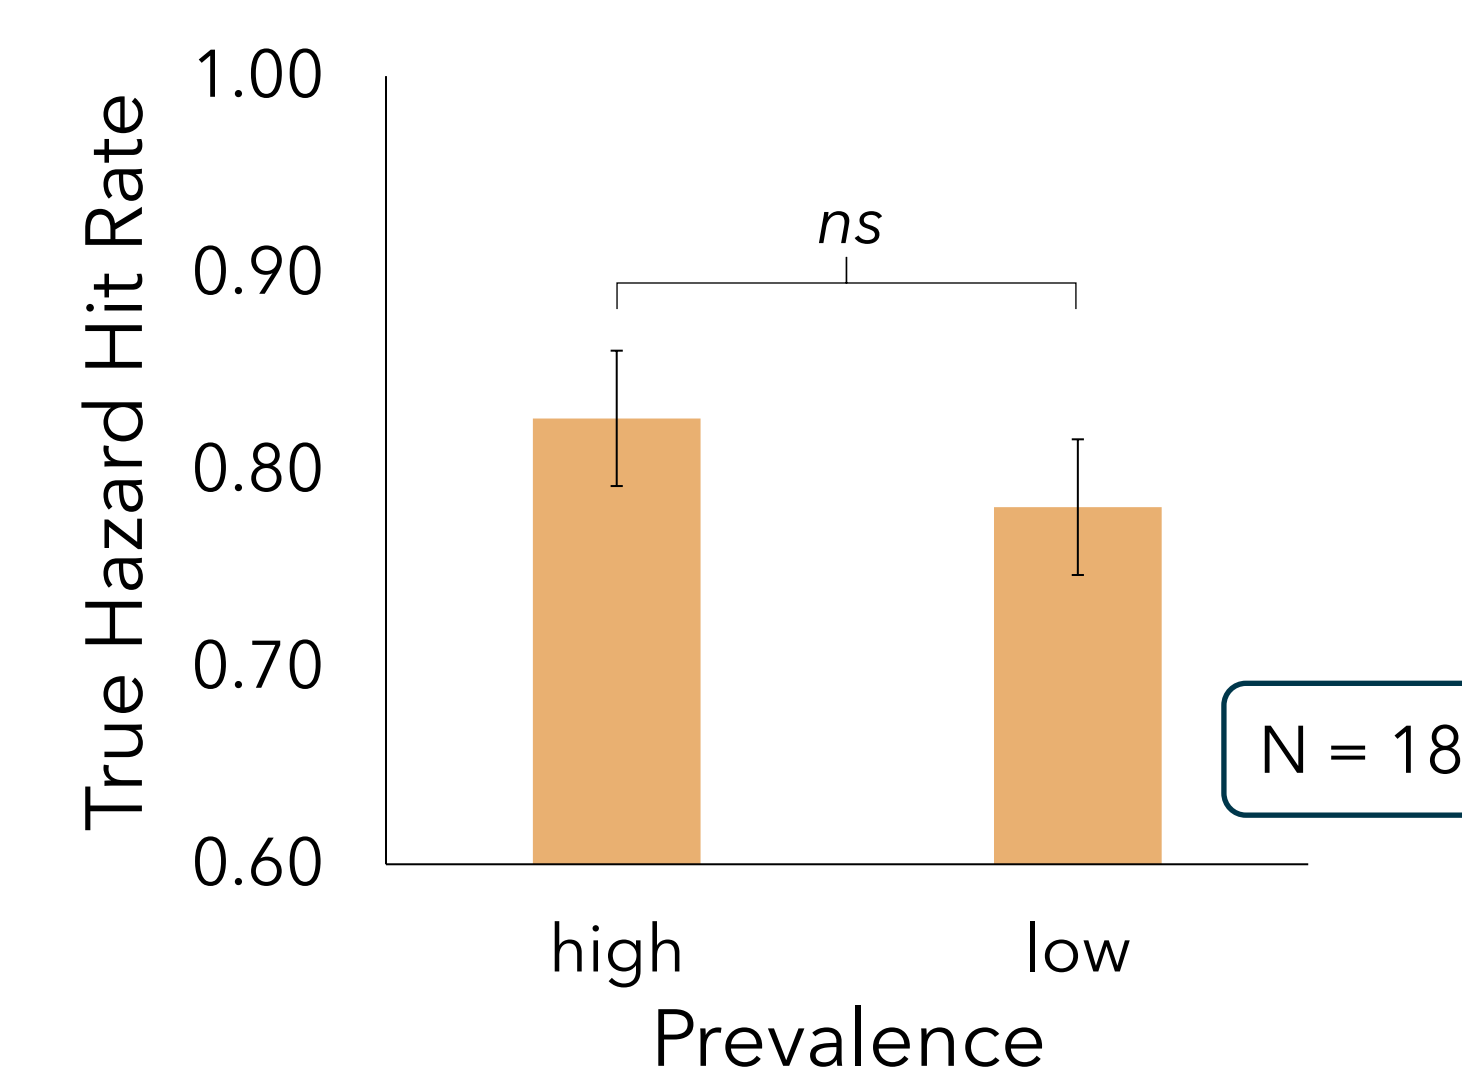

Less likely to classify a "true-T" as a T when successfully found during periods of low prevalence

The LPE for similarity search and binary decision tasks are not correlated,  $r^2 = .02$  (ns)  
Separate decision-making processes for similarity search and binary decision tasks?

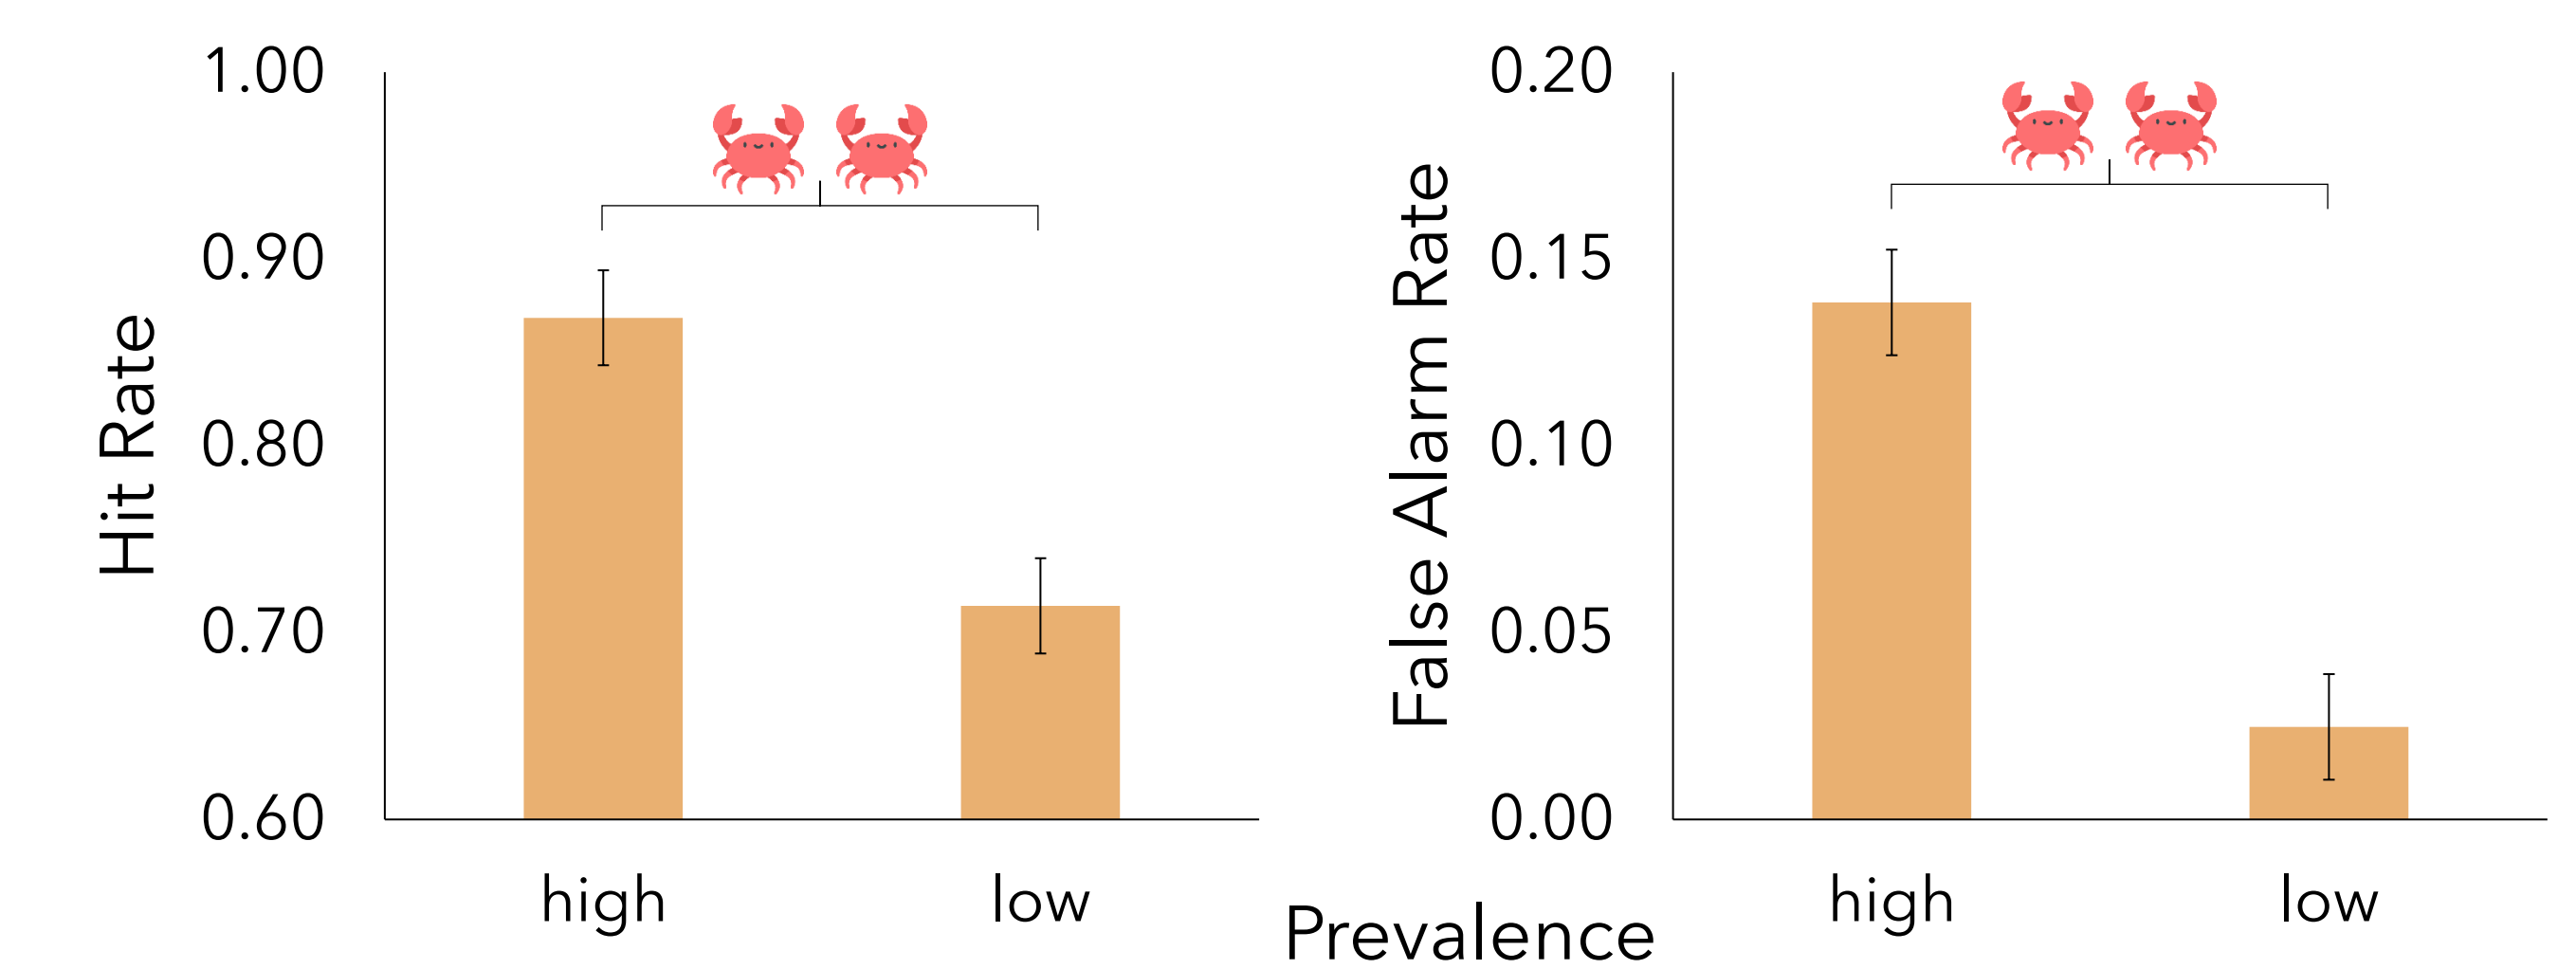

## Experiment 2 Results

### Hazard Localization Performance

No LPE: Participants were equally likely to click on the hazards on hazard-present trials

### Binary Decision Performance

Hazards selected in the localization task were less likely to be judged as requiring a response under low prevalence

The difference in hit rate between the prevalence conditions on the hazard localization and binary decision tasks are not correlated,  $r^2 = .05$  (ns)

## Conclusions

- In some situations, similarity search can help observers locate targets during periods of low target prevalence
- However, this did not translate to the binary decision task
- Lack of correlation between search/localization + binary decisions suggests these may be two distinct decision-making processes
